## Linear regression is flexible!

## Some simple transformations

- The linear model we are using consists of making the parameters of probability distributions change according to some function
- The simplest function is a linear function

- Sometimes the relation between parameters and predictors is not linear
- We can use whatever functional shape we like, but it is useful to use transformations to linearize the relation

$$y_i \sim N(\mu_i, \sigma)$$

$$\mu_i = \alpha + \beta x_i$$

$$\log(y_i) \sim N(\mu_i, \sigma)$$

$$\mu_i = \alpha + \beta x_i$$

## Log transforming the response

## Multiplicative increments

- The **logarithmic transformation** of the response is a common transformation when the effect of the predictor on the response is thought to be multiplicative
  - A change of a unit in x is associated with a constant percentage change in y
- Many processes benefit from log transformation:
  - Growth is proportional do previous size
  - Any multiplicative process
